Independent and Dependent Variables

The only dependent variable is t(time) measured in days.

The first set of dependent variables are functions of time, which count people in each group.

S(t) is the number of *susceptible* individuals at given time,

I(t) is the number of *infected* individuals at give time,

R(t) is the number of *recovered* individuals at give time.

Simulation Results on Real-World

Simulations on USA's COVID-19 Data Simulations on Armenia's

The second set of dependent variables represents the fraction of the total population in each of the three categories. So, if N is the total population we have:

$$s(t) = \frac{S(t)}{N}$$
 the susceptible fraction of the population,

$$i(t) = \frac{I(t)}{N}$$
 the *infected fraction* of the population, and

$$r(t) = \frac{R(t)}{N}$$
 the recovered fraction of the population.

$$\frac{\partial s}{\partial t} = -\beta s(t)i(t)$$

$$\frac{\partial r}{\partial t} = \gamma i(t)$$

$$\frac{\partial s}{\partial t} = -\beta s(t)i(t) \tag{1}$$

$$\frac{\partial r}{\partial t} = \gamma i(t) \tag{2}$$

As the sum of susceptable, infected and recovered people gives the whole population, it means that

$$\frac{\partial s}{\partial t} + \frac{\partial i}{\partial t} + \frac{\partial r}{\partial t} = 0 \tag{3}$$

To get the differential equation for infecteds it is enough to plug equations (1) and (2) into equation (3). The result will be:

$$\frac{\partial i}{\partial t} = -\beta s(t)i(t) - \gamma i(t)$$

$$(4)$$

Simulations on USA's COVID-19 Data Simulations on Armenia's

Combining all three equations will give the following system of differential equations:

$$\begin{cases} \frac{\partial s}{\partial t} = -\beta s(t)i(t) \\ \frac{\partial i}{\partial t} = -\beta s(t)i(t) - \gamma i(t) \\ \frac{\partial r}{\partial t} = \gamma i(t) \end{cases}$$

Analytical Solution

Analytical Solution

Mathematical Theory of Infectious Disease **Epidemics**

G. Hovhannisyan A. Abrahamyan M. Khachatryan

Analytical Solution

Step 1) Differentiating x with respect to time t, and substituting y'.

$$x'' = -\beta \left(x' \left(\frac{-x'}{\beta x} \right) + xy' \right) \implies \frac{-x''}{\beta} = \frac{-(x')^2}{\beta x} + xy'$$

$$\implies xy' = \frac{-x''}{\beta} + \frac{-(x')^2}{\beta x}$$

$$\implies y' = \frac{-1}{\beta} \left(\frac{-x''}{x} - \left(\frac{x'}{x} \right)^2 \right)$$

$$-x' + \frac{\gamma x'}{\beta x} = \frac{-1}{\beta} \left(\frac{-x''}{x} - \left(\frac{x'}{x} \right)^2 \right)$$

$$\implies \beta x' - \frac{\gamma x'}{x} = \frac{x''}{x} - \left(\frac{x'}{x} \right)^2$$

$$\implies \frac{x''}{x} - \left(\frac{x'}{x} \right)^2 + \frac{\gamma x'}{x} - \beta x' = 0$$

Step 3) We also have that $y = \frac{-x'}{\beta x}$ and $y = \frac{z'}{\gamma}$. Equating them we get

$$\frac{-x'}{\beta x} = \frac{z'}{\gamma} \implies z' = -\frac{\gamma}{\beta} \left(\frac{x'}{x} \right)$$

Analytical Solution

Step 4) Next we integrate Step (3)

$$c_1 + z = -\frac{\gamma}{\beta} \int \frac{x'}{x} dt \implies c_1 + z = -\frac{\gamma}{\beta} (\ln(x) + c_2)$$

$$\implies \ln(x) = -\frac{\beta c_1}{\gamma} - \frac{\beta z}{\gamma} - c_2$$

$$\implies x = e^{-\frac{\beta z}{\gamma}} \cdot e^{-\frac{\beta c_1}{\gamma} - c_2}$$

$$\implies x = x_0 e^{-\frac{\beta z}{\gamma}}$$

Where x_0 is an integration constant.

Step 5) From Step(4) we get that

$$x' = -\frac{x_0 \beta}{\gamma} z' e^{-\frac{\beta z}{\gamma}}$$

Step 6) Instead of integrating we differentiate Step (3) and get

$$z'' = -\frac{\gamma}{\beta} \left(\frac{x''}{x} - \left(\frac{x'}{x} \right)^2 \right)$$

Step 7) Finally if we combine Step(6), Step(5) and Step(3) into Step(2) we get

$$z'' = x_0 \beta z' e^{-\frac{\beta z}{\gamma}} - \gamma z'$$

on Real-World Data

Simulations on USA's COVID-19 Data Simulations on Armenia's

All the other steps can be found in the paper in Appendix B, but eventually we get the parametric form

$$x = x_0 u,$$

$$y = \frac{\gamma}{\beta} \ln u - x_0 u - \frac{C_1}{\beta},$$

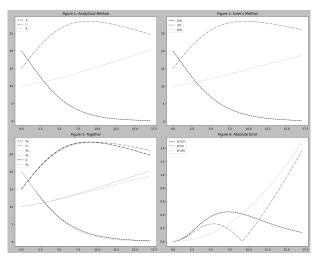

$$z = -\frac{\gamma}{\beta} \ln u$$

Where $u_0 = e^{-\frac{\beta}{\gamma}N_3}$, $C_1 = -\beta N$. And the relation between u and t being as follows

$$t = \int_{u_0}^u \frac{du}{u(C_1 - \gamma \ln u + x_0 \beta u)}$$

Fuler's Method

Fuler's Method

By using the extension $y'_{k} = \frac{y_{k+h} - y_{k}}{h}$ and having the y_{0} , we can iteratively predict the $y_{k+1} = y(x+h)$, by using the system

$$\begin{cases} \frac{y_{k+1}-y_k}{h} = f(x_k, y_k) \\ y(x_0) = y_0 \end{cases}$$

In case of SIR, we are solving 3 ODE's, hence we are solving a system for s_{k+1} , i_{k+1} , and r_{k+1} , given the s_0 , i_0 , r_0

$$\begin{cases} s_{k+1} = s_k - \beta \cdot h \cdot s_k \cdot i_k \\ i_{k+1} = i_k + (\beta \cdot s_k \cdot i_k - \gamma \cdot i_k) \cdot h \\ r_{k+1} = r_k + \gamma \cdot h \cdot i_k \end{cases}$$

This time, the Method uses a different approach, namely

$$y'(x) \approx \frac{y_n - y_{n+1}}{h}$$

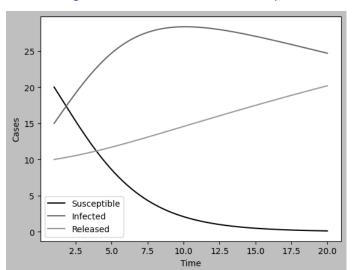

Plugging the SIR ODE's, we will get the system

$$\begin{cases} s_{t+1} = s_t - h \cdot \beta s_{t+1} i_{t+1} \\ i_{t+1} = i_t + h \cdot (\beta s_{t+1} i_{t+1} - \gamma i_{t+1}) \\ r_{t+1} = r_t + h \cdot \gamma i_{t+1} \end{cases}$$

By solving each one of these SLE's, we will get the next approximations for s_k , i_k , r_k
